# Population ecology: overview

- *Population*

- Group of individuals of same species in same area at same time

- *Population ecology*

- Study of how and why a population changes over time
- Utilizes mathematics as predictive tool

# Demography

- *Demography*

- ▣ Study of factors that determine size and structure of populations through time

- Populations grow

- ▣ Birth

- ▣ Immigration

$$P_2 = P_1 + (B + I - D - E)$$

- Populations decline

- ▣ Death

- ▣ Emigration

# Survivorship curve

- Proportion of offspring that survive at specific age
  - ▣ Logarithm of number of survivors vs. age
- Type
  - ▣ Type I curve
    - Survivorship high throughout life
    - Humans
  - ▣ Type II curve
    - Survivorship constant over life
    - Songbirds
  - ▣ Type III curve
    - High death rates early
    - High survivorship after maturity
    - Trees

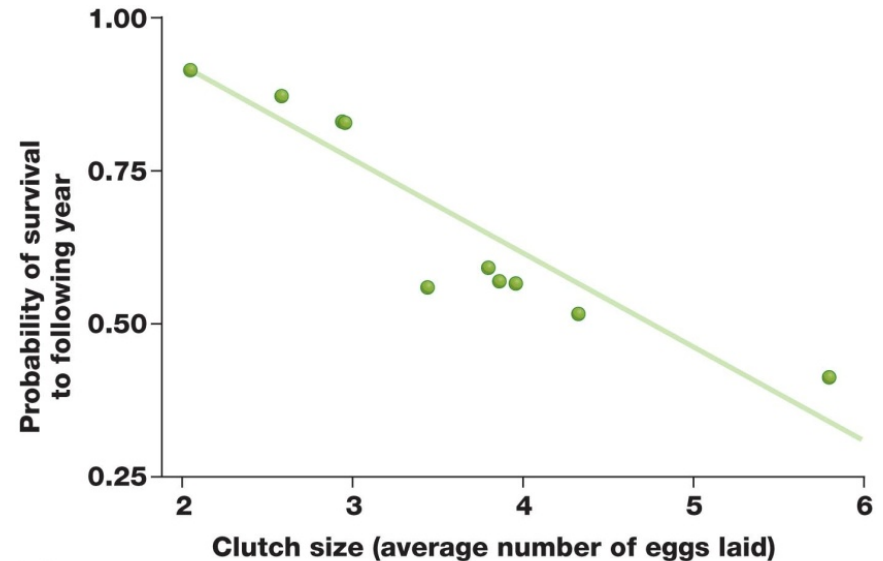

# Fecundity

- The number of offspring produced by each female a population
- Survivorship curve and fecundity useful in calculating growth rate of population

# Fitness trade-offs

- Resources are limited
  - Limited E
  - Female can:
    - Maximize fecundity
    - Maximize survivorship
    - Balance the two
  - Resource allocation

# Population growth

- Growth rate ( $r$ ) is function of
  - ▣ Change individuals of population ( $\Delta N$ ) per unit time ( $\Delta t$ )

$$r = \Delta N / \Delta t = (b - d)$$

- ▣  $r$  varies through time
  - Positive: growing
  - Negative: declining
  - Neutral: no growth

# Exponential growth

# Exponential growth

- Occurs when  $r$  doesn't change over time
  - ▣ *Density independent*
    - Doesn't depend on number of individuals in population
- Observed in:
  1. Founding of new habitat
  2. Population devastated (e.g. hurricane) & recovers from few individuals
- Can't continue forever
  - ▣ Population density gets too high ( $r$  declines)
    - *Density dependent*

# Logistic growth

- *Carrying capacity ( $K$ )*

- ▣ Maximum individuals that are sustainable over time

- ▣ If population  $< K$

- Population grows

- ▣ If population  $> K$

- Population decreases

- *Logistic growth equation*

- ▣ Density dependent

# Logistic growth

- $r$  phase
  - ▣ Growth is exponential
  - ▣  $r$  is constant
- Density-dependency
  - ▣  $r$  declines when  $N$  increases
- $K$  phase
  - ▣  $r$  reaches zero at  $K$

# Density dependence

- Key factor of  $K$
- Factors of density dependence
  - ▣ Over-exploitation of resources (food, space, light)
  - ▣ Predation

# Carrying capacity varies

- $K$  is not fixed in type
  - ▣ Varies among spp. & populations
- $K$  is not fixed in space
  - ▣ Varies among habitats
  - ▣ Food availability, space, etc
- $K$  is not fixed time
  - ▣ Some years are better

# Metapopulations

A metapopulation is made up of small, isolated populations.

- Population of populations
- Patches go extinct, redevelop, and are reestablished over time

Although some subpopulations go extinct over time...

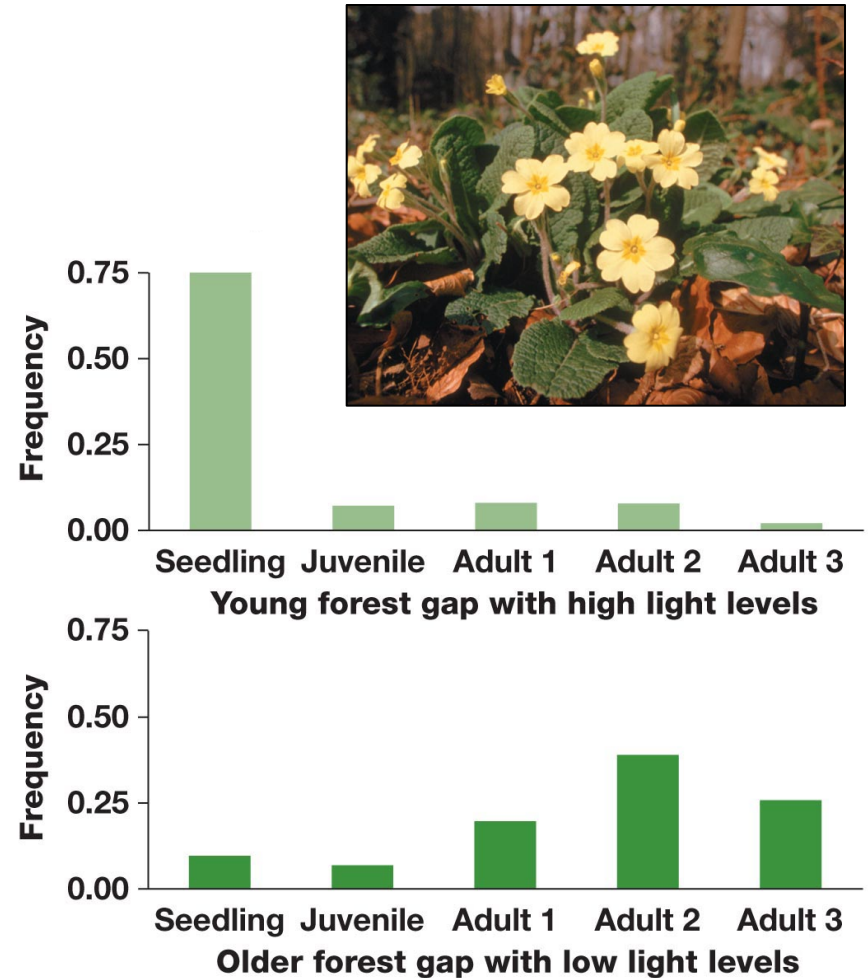

...migration can restore or establish subpopulations.

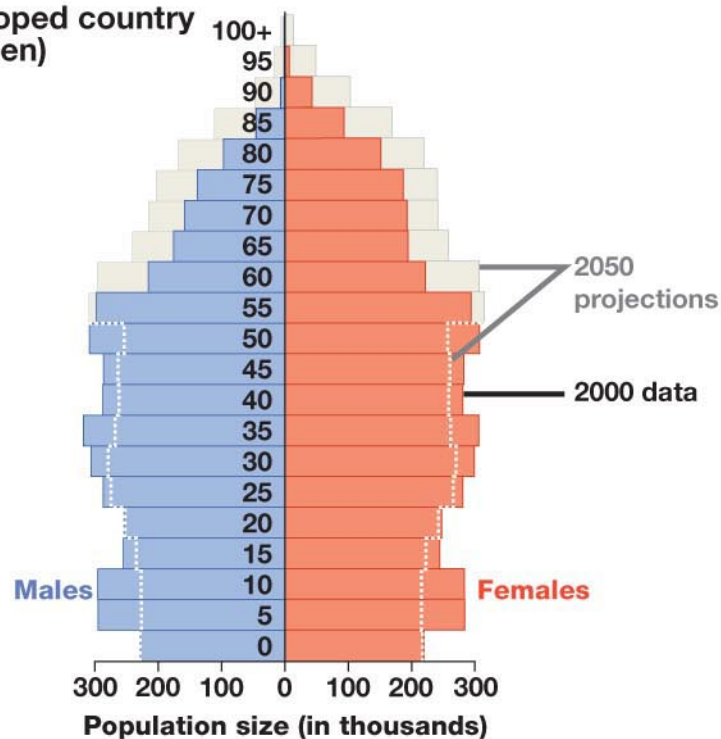

# Age structure

- Proportion of individuals at each age group
- Affects population's growth over time
- Varies over time
  - Common primrose
    - New tree gaps have rapidly growing juveniles
    - As tree grows, population declines leaving mostly adults

# Human age structure

(a) Developed country  
(Sweden)

(b) Developing country  
(Honduras)

# Human population growth rate

- Current estimate: 7 billion

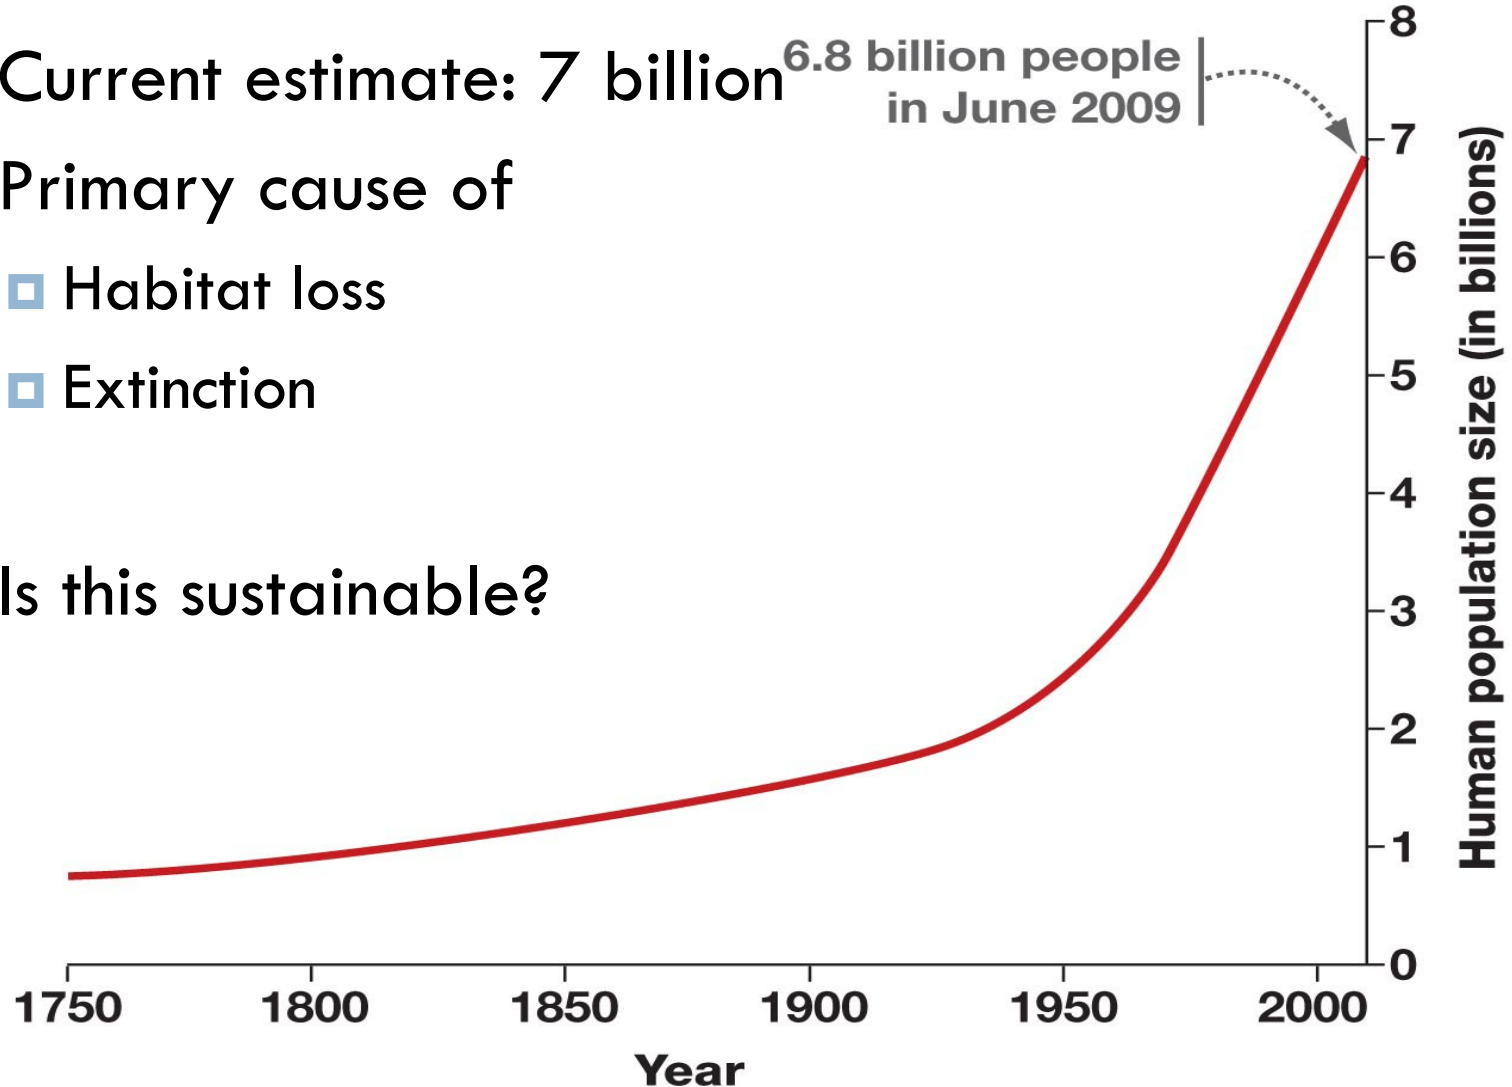

6.8 billion people  
in June 2009

- Primary cause of

  - Habitat loss

  - Extinction

- Is this sustainable?

# Human population growth rate

- Dependent on fertility rates
- Has it peaked?
  - ▣ Since 1970 growth rate dropping
  - ▣ 1990-95: 1.46%
  - ▣ Now: 1.2%
