

# SPECIATION

This presentation contains copyrighted material under the educational fair use exemption to the U.S. copyright law.

# Speciation

- Divergence
  - ▣ If gene flow ends, isolated populations diverge
- Divergence can lead to speciation
  - ▣ Ancestral groups to 2+ species

# Biological species concept

- Species are...
  - ▣ Populations that are reproductively isolated from each other
- No gene flow b/n populations
  - ▣ Do not interbreed
  - ▣ Fail to produce viable, fertile offspring

# Biological Species Concept

## □ Advantages

- Applicable to many ecological studies
- Can define different spp. that may be morphologically similar

# Biological species concept

- Disadvantages
  - ▣ Can't be evaluated in fossil record
  - ▣ Ignores asexual species
  - ▣ Only applied to populations that geographically overlap

# Morphospecies concept

- Species are...
  - ▣ Different in morphological lineages
- Different morphological features arise
  - ▣ Populations are independent
  - ▣ Isolated from gene flow

# Morphospecies concept

## □ Advantages

- ▣ Can be used with the fossil record
- ▣ Can easily identify spp. in the field
- ▣ Doesn't require geographic overlap

# Morphospecies concept

## Disadvantages

- ❑ Can't identify species not morphologically different
- ❑ Morphological features are subjective
- ❑ Variation exists in populations

# Phylogenetic species concept

- Based on reconstructing evolutionary history of populations
- Species are defined as the smallest monophyletic group

- **Monophyletic group:** an ancestral population and all descendants
- **Synapomorphy:** trait unique to a monophyletic group

# Phylogenetic species concept

## □ Advantages

- ▣ Can lead to very precise definitions of taxa
  - Even if they look similar
- ▣ Can validate (or invalidate) previously established taxa
  - Split (into 2+ spp.)
  - Lumped (into 1 sp.)
- ▣ Creates phylogenies based on data (not assumptions)

# Phylogenetic species concept

# Phylogenetic species concept

## ❑ Disadvantages

- ❑ Leads to recognition of many more species
- ❑ Difficult to identify species in the field
- ❑ Incomplete phylogenies for many groups

# Subspecies

- Populations in discrete geographic areas
- Very little gene flow
- Specific in traits

# Isolation and Divergence

- Genetic isolation from physical isolation

- Dispersal

- Population moves to new area

- Vicariance

- Physical barrier splits

# Vicariance

- Physical isolation of populations

Abert's squirrel

Kiabab squirrel

# Allopatric speciation

- Speciation from physical separation
- Mechanisms
  - ▣ Dispersal
  - ▣ Vicariance

# Sympatric speciation

- Speciation without geographic isolation
- Originally thought to be impossible
  - ▣ Gene flow would overwhelm genetic drift
- Can happen
  - ▣ Preferences in a habitat

## PROCESS: SYMPATRIC SPECIATION

# Sympatric speciation

**Apple flies**

**Percent of individuals that fly to scent ( $n = 129$ )**

**Hawthorn flies**

**Percent of individuals that fly to scent ( $n = 203$ )**

# Polyploidy

- Mutations that lead to individuals having more than one set of chromosomes
  - ▣  $4n$  instead of  $2n$
  - ▣ tetraploid
- Common in plants
- Can cause rapid speciation

# Ployploidy

- Diploids can't mate with tetraploids
  - Produce triploids
  - Reproductively isolated

# Autopolyploidy

- Polyploidy of same species
- $4n$  maidenhair ferns
  - ▣ Produced diploid gametes
- $4n$  populations genetically isolated from  $2n$
- Divergence begins
- Sympatric speciation possible

# Allopolyploidy

- Chromosomes derived from different spp.
- New tetraploid ( $4n$ ) species (hybrid)
  - ▣ From diploid hybridization
  - ▣ When diploid gamete fuse

# Why polyploidy in plants?

- Self-fertilize
  - ▣ Diploid gametes can fuse
- Hybridization is common
  - ▣ Creating opportunity for allopolyploidy

# When isolated populations contact

- Depends how far populations have diverged genetically
  - ▣ Large divergence
    - Mating rare
    - Gene flow minimized
    - Populations continue to diverge
  - ▣ “Insignificant” divergence
    - Mating frequency increases
    - Gene flow increases
    - Populations converge

# When isolated species contact

- Geographic area where interbreeding of two species occur
- Hybridization
  - Commonly leads to local extinction
  - Sometimes origination of new species
